(54) Title: MAGNETIC RECORDING HEAD INCLUDING BACKGROUND MAGNETIC FIELD GENERATOR

(57) Abstract: A perpendicular recording head (10) for use with magnetic recording media (30) includes a main pole (14) and a magnetic field source which is positioned sufficiently close to the main pole tip to generate a background magnetic field in the recording media. A conductive magnetizing coil (20) surrounding the main pole is preferably used as the magnetic field source. The background magnetic field generated by the magnetizing coil effectively reduces the coercivity of the magnetic recording media in the region affected by the background field. The recording head enables writing on high coercivity/high anisotropy magnetic media, thereby achieving extremely high recording densities.

MAGNETIC RECORDING HEAD INCLUDING BACKGROUND MAGNETIC FIELD GENERATOR

CROSS REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional Patent Application
5 No. 60/154,880, filed September 20, 1999.

FIELD OF THE INVENTION

The present invention relates to recording heads for use with magnetic
storage media, and more particularly relates to a perpendicular recording head which
generates a background magnetic field in the magnetic media.

BACKGROUND INFORMATION

10 Perpendicular magnetic recording heads have been developed for use in
hard disk drive systems. Some examples of perpendicular recording heads are described
in U.S. Patent Nos. 4,438,471 to Ashiki et al., 4,541,026 to Bonin et al., 4,546,398 to
Toda et al., 4,575,777 to Hosokawa, 4,613,918 to Kanai et al., 4,649,449 to Sawada et
15 al., 4,731,157 to Lazzari, 4,974,110 to Kanamine et al., and 5,738,927 to Nakamura et
al.

In order to increase the data storage density of hard disk drives, the use of
magnetic media having increased magnetic anisotropy has been proposed. However,
highly anisotropic media exhibit extremely high coercivities, e.g., well over 5,000 Oe.
20 Conventional perpendicular magnetic recording heads are not capable of recording on
media having such high coercivities.

The present invention has been developed in view of the foregoing, and to
address other deficiencies of the prior art.

SUMMARY OF THE INVENTION

25 The present invention provides a magnetic recording head for use with
magnetic recording media having a magnetic field generating coil configured and
positioned to generate a background magnetic field in the magnetic recording media.
The magnetic recording head preferably comprises a perpendicular configuration. In

accordance with the present invention, the perpendicular recording head generates a supplemental magnetic field which increases the magnetic recording field in comparison with conventional perpendicular recording heads. Although not limited to such use, perpendicular recording heads of the present invention are particularly useful for computer hard disk drives.

A typical perpendicular recording head includes a main pole, an opposing pole magnetically coupled to the main pole, and an electrically conductive magnetizing coil surrounding the main pole. The bottom of the opposing pole will typically have a surface area greatly exceeding the surface area of the tip of the main pole. In a preferred embodiment, electrical current flowing through the magnetizing coil creates a flux through the main pole tip and also generates the background magnetic field in the recording media.

A typical magnetic recording medium for use in conjunction with the present perpendicular recording head includes an upper layer having multiple magnetically permeable tracks separated by nonmagnetic transitions, and a magnetically permeable lower level. The lower level is magnetically soft relative to the tracks.

To write to the magnetic recording medium, the recording head is separated from the magnetic recording medium by a distance known as the flying height. The magnetic recording medium is moved past the recording head so that the recording head follows the tracks of the magnetic recording medium, with the magnetic recording medium first passing under the opposing pole and then passing under the main pole. Current is passed through the coil to create magnetic flux within the main pole. The magnetic flux will pass from the main pole tip through the track, into the lower layer, and across to the opposing pole. In addition to the magnetic field generated at the main pole tip, a supplemental magnetic field is generated in accordance with the present invention. The combined magnetic flux from the pole tip and from the coil causes the magnetic fields in the tracks to align with the magnetic flux of the recording head. Changing the direction of electric current changes the direction of the flux created by the recording head and therefore the magnetic fields within the magnetic recording medium.

An aspect of the present invention is to provide a perpendicular recording head including a main pole having a tip, and an electrically conductive magnetizing coil

- 3 -

positioned sufficiently close the main pole tip to generate a background magnetic field in the magnetic recording medium when current is passed through the magnetizing coil.

Another aspect of the present invention is to provide a magnetic recording apparatus comprising a magnetic recording medium and a recording head. The magnetic recording medium includes an upper layer having a plurality of data storage tracks, and a lower layer being magnetically soft relative to the data storage tracks. The recording head includes a main pole having a tip, and an electrically conductive magnetizing coil positioned sufficiently close the main pole tip to generate a background magnetic field in the magnetic recording medium when the recording head is positioned at a flying height above the magnetic recording medium and current is passed through the magnetizing coil.

A further aspect of the present invention is to provide a method of storing data on a magnetic storage medium. The method includes the steps of providing a magnetically permeable main pole, providing a magnetic storage medium adjacent the main pole, directing magnetic flux from the main pole toward the magnetic storage medium, and additionally generating a background magnetic field in the magnetic storage medium.

These and other aspects of the present invention will be more apparent from the following description.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a graph of magnetic field strength versus distance from the air bearing surface of a conventional perpendicular recording head, illustrating a substantial drop-off in magnetic field strength as the distance is increased.

Fig. 5 is a partially schematic side sectional view of a perpendicular recording head pole tip and magnetic coil configuration in accordance with another embodiment of the present invention.

Fig. 6 is a graph comparing magnetic flux density of a perpendicular recording head with and without the generation of a background magnetic field.

Fig. 7 is partially schematic side sectional view of a test apparatus for generating a background magnetic field in accordance with the present invention.

Fig. 8 is a graph of playback level versus time, showing the effectiveness of the test apparatus illustrated in Fig. 7.

DETAILED DESCRIPTION

The preferred embodiment of the present invention provides a perpendicular recording head for use with magnetic recording media. As used herein, "recording head" means a head adapted for read and/or write operations.

The present invention has been developed in order to overcome certain problems with conventional hard disk drive systems. Granular magnetic recording media used in such systems is subject to superparamagnetic instabilities when the anisotropy energy of the grains ($K_u \times V$, where V is the grain volume) becomes comparable to the energy of thermal fluctuations, kT . Improvements in recording densities requires continuous refinement of the grain size. Higher anisotropy materials are desirable in order to keep the media thermally stable. As an example, the L10 phase of $\text{Co}_{50}\text{Pt}_{50}$ has an anisotropy energy $K_u = 4 \times 10^6 \text{ J/m}^3$ (compare with $K_u = \sim 10^5 \text{ J/m}^3$ for CoCr media). Such high anisotropy reduces the critical size at which grains become thermally unstable to less than 1 nm. Utilizing these materials for recording media can potentially extend the recording densities well beyond 100 Gbit/in². However, a major obstacle preventing utilization of high anisotropy media is that such media exhibit exceptionally high coercivities, e.g., in excess of 5,000 Oe.

The magnitude of the fields generated by conventional perpendicular recording heads is limited by the saturation moment of the yoke material. Fig. 1 is a graph illustrating the dependence of magnet field strength on the distance from the pole tip or air-bearing surface (ABS) for a conventional single-pole perpendicular head

utilizing FeAlN (saturation moment of 2Tesla) as the pole material. At distances greater than 15 nm from the ABS, the field drops below 5,000 Oe. This arrangement is therefore not sufficient for recording on media with coercivities of 5,000 Oe and higher.

Fig. 2 schematically illustrates a single pole perpendicular recording head 10 in accordance with an embodiment of the present invention. The perpendicular recording head 10 includes a yoke 12 made of magnetically permeable material such as NiFe, CoZrNb, CoZrTa, CoNiFe, FeAlN, FeTaN, CoFe, CoFeB or any other soft magnetic materials, including multiple layers or laminates of such materials. A main pole 14 extends from the yoke 12 and includes a main pole tip 16. The main pole 14 may be made of any suitable magnetically permeable material such as NiFe, FeAlN, FeTaN, CoFe, CoFeB, CoFeN or any other soft magnetic materials, including multiple layers of such materials. An opposing pole 18 is magnetically coupled to the main pole 14. In accordance with the present invention, an electrically conductive magnetizing coil 20 surrounds the yoke 12 and main pole 14. As shown in Fig. 2, the magnetizing coil 20 is located close to the main pole tip 16. Electrical current is supplied to the coil 20 through electrical connections 22. The magnetizing coil 20 may be made of any suitable electrically conductive material, such as Cu, Ag, Au or any other high conductivity materials or alloys.

As shown in Fig. 2, the perpendicular recording head 10 is positioned above a magnetic storage media including a hard magnetic recording layer 30 and a soft magnetic underlayer 32. A protective overcoat 33 such as diamond-like carbon is applied over the recording layer 30. During recording operations, the magnetic media moves in the direction of the arrow shown in Fig. 2.

The recording layer 30 may be made of any suitable hard magnetic material such as CoCrPt, CoCrPtTa, CoCrPtB, CoCrPtTa Nb or other high anisotropy hexagonal Co-containing alloys. The recording layer 30 may also be made of CoPt, FePt, CoPd, FePd or other high anisotropy L10 materials. High anisotropy materials such as Co/Pd, CoB/Pd, CoCr/Pd, CoCrPt/Pd, CoCrPd/Pt, CoB/Pt, Co/Pt, CoCr/Pt, Fe/Pd and Fe/Pt may also be used as the recording layer 30. Furthermore, high anisotropy ferrites such as Ba ferrite may be used as the recording layer 30. Preferred materials for the recording layer 30 include L10 materials such as CoPt, FePt, CoPd and

FePd, and multilayers of Co/Pt and Co/Pd. The recording layer may have a relatively high anisotropy energy K_u , e.g., greater than about 10^6 J/m³. For example, recording layers having anisotropy energy K_u levels of from about 10^6 to about 10^8 J/m³ may be used. The recording layer may also have a relatively high coercivity above 5,000 Oe, e.g., above 8,000 or 10,000 Oe. The underlayer 32 may be made of any suitable soft magnetic material, such as FeAlN, FeTaN, CoFe, CoFeB, CoFeN or other high moment soft magnetic materials or soft magnetic films comprising multiple layers of such materials.

Fig. 3 is an enlarged view of a portion of the perpendicular recording head 10 of Fig. 2, showing dimensional details of the yoke 12, main pole 14 and magnetizing coil 20. The magnetizing coil 20 has a radial dimension R measured from the center of the yoke 12 or the longitudinal axis of the main pole 14. The coil 20 is located at a distance D from the main pole tip 16, measured in a direction parallel with the longitudinal axis of the main pole 14 (normal to the surface of the recording layer 30). The main pole tip 16 is located at a flying height H above the upper surface of the protective layer 33. The main pole tip 16 preferably forms part of the air bearing surface of the recording head 10. The magnetizing coil 20 is positioned at a distance Z from the upper surface of the recording layer 30, measured in a direction parallel with the longitudinal axis of the main pole 14. The distance Z is equal to the sum of the distances D and H , plus the thickness of the protective layer 33. As further shown in Fig. 3, the yoke 12 has a thickness T_y which is preferably larger than the thickness T_p of the main pole 14.

The dimensions R , D , H , Z , T_y and T_p are preferably selected in accordance with the present invention to produce a sufficient background magnetic field in the recording layer 30 when current flows through the coil 20. For many perpendicular recording head configurations, R preferably ranges from about 0.1 to about 5 micron, D ranges from about 0.1 to about 5 micron, H ranges from zero to about 0.1 micron, and Z ranges from about 0.1 to about 5 micron. The yoke thickness T_y may typically be from about 0.1 to about 5 micron, preferably from about 0.1 to about 1 micron. The main pole thickness T_p may be from about 0.01 to about 0.5 micron, preferably from about 0.01 to about 0.1 micron.

In accordance with the present invention, the ratio of the coil radial dimension R to the distance D is preferably controlled in order to generate the desired background magnetic field in the recording layer 30, as more fully described below. The ratio of R:D typically ranges from about 1:1 to about 10:1, preferably from about 1:1 to about 5:1. The ratio of the yoke thickness T_y to the pole thickness T_p is also controlled. The ratio of $T_y:T_p$ preferably ranges from about 1:1 to about 10:1. More preferably, the ratio of $T_y:T_p$ ranges from about 2:1 to about 5:1.

Although the magnetizing coil 20 shown in Figs. 2 and 3 comprises a single circular winding, multiple windings and/or other coil shapes may be used. For example, the coil 20 may alternatively be square, rectangular, helical, straight, etc. Similarly, the cross-sectional shapes of the yoke 12 and main pole 14 may be round, square, rectangular, or the like. The magnetizing coil 20 preferably surrounds the yoke 12 and main pole 14 as shown in Figs. 2 and 3. However, the coil could be located at a different position on the head 10 as long as a sufficient background magnetic field is generated. Furthermore, although not preferred, a permanent magnet could be used in place of, or in addition to, the coil 20.

Figs. 4 and 5 schematically illustrate alternative coil configurations in accordance with the present invention. In the embodiment shown in Fig. 4, an electrically conductive magnetizing coil 24 surrounds and is positioned directly adjacent the outer surface of the yoke 12. In the embodiment shown in Fig. 5, an electrically conductive magnetizing coil 26 surrounds and is embedded in a recess 28 which extends around the outer surface of the yoke 12. In Figs. 4 and 5, each of the magnetizing coils 24 and 26 is shown as a single winding around the yoke 12. Alternatively, multiple coil windings may be used. Although the magnetizing coils 24 and 26 shown in Figs. 4 and 5 have square cross sections, any other suitable sectional shape may be used, such as rectangular, circular, etc. The cross-sectional thickness of the magnetizing coils 20, 24 and 26 typically ranges from about 0.01 to about 5 micron, preferably from about 0.1 to 2 micron.

In the embodiments shown in Figs. 2-5, the pole tip 16 comprises a flat surface. Alternatively, the present design can be combined with a perpendicular head having a concave pole tip design, such as the concave pole tips described in U.S. Patent

Application Serial No. _____, filed September 19, 2000 entitled Perpendicular Recording Head Including Concave Tip, which is incorporated herein by reference.

5 In accordance with the present invention, the amount of electrical current supplied to the magnetizing coil 20 is controlled in order to generate the desired background magnetic field strength at the recording layer 30. The background magnetic field is typically greater than 100 Gauss, preferably greater than 1,000 or 2,000 Gauss. Depending upon the magnetic properties of the recording layer 30, the background magnetic field may typically range from about 100 to about 20,000 Gauss, preferably
10 from about 1,000 to about 15,000 Gauss, and more preferably from about 5,000 to about 10,000 Gauss at the recording layer 30. The background magnetic field effectively decreases the coercivity of the recording layer 30. The coercivity of the recording layer 30 may be defined as H_c , and the background magnetic field effectively decreases the coercivity H_c to a lower value defined as H_b . The ratio of $H_b:H_c$
15 preferably ranges from about 1:10 to about 9:10, more preferably from about 3:10 to about 8:10. In a particularly preferred embodiment, the ratio of $H_b:H_c$ is about 5:10.

In accordance with a further aspect of the present invention, the level of the background magnetic field H_b is controlled in relation to the strength of the magnetic field H_p generated at the main pole tip 16. Preferably, the ratio of $H_b:H_p$ is from about
20 1:10 to about 10:1, more preferably from about 4:10 to about 3:1. As a particular example, a recording layer having a coercivity of 10,000 Oe may be written on with a recording head of the present invention which generates a pole tip coercivity H_p of 5,000 Oe and a background coercivity H_b of 8,000 Oe. Thus, while the magnetic flux generated from the pole tip would not be sufficient to write on the recording layer alone,
25 the background magnetic field is sufficient to effectively reduce the dynamic coercivity of the recording layer, thereby enabling writing on the recording layer.

As long as the pole tip is not completely saturated, the magnetic flux is mainly concentrated within the pole tip. A standard way of operating a single pole head is to choose a current value I_{SAT} that causes complete saturation of the pole tip. The
30 fields generated by the saturated pole are localized and their gradients within the recording layer determine the minimum bit cell size. If the current in the coil is further

increased by ΔI ($\Delta I = I - I_{SAT}$), the extra flux generated will no longer be confined to the pole tip. The magnitude of the additional field ΔB will be proportional to ΔI . The field flux will be spread over a significantly larger region within the recording layer, the size of which is determined by the diameter of the coil due to the relative proximity of the coil to the recording layer. The magnitude of ΔB can be fine-tuned by the current in the coil. For a single turn coil the magnitude of ΔB is given by:

$$\Delta B = \frac{\mu_0 \Delta I}{2} \frac{R^2}{(R^2 + z^2)^{3/2}},$$

where R is the radius of the coil and z is the distance from the coil to the hard layer.

For $R=0.2 \mu\text{m}$ and $z=0.1 \mu\text{m}$, background fields in excess of 1 Tesla (10,000 Oe) can be generated with currents as small as 400 mA with a resolution of about 25 Oe/mA if a single turn coil is used.

The presence of the additional background field ΔB effectively reduces coercivity of the recording layer. It enables writing on high coercivity media using heads based on available soft materials. Because of high data rates, the dynamic coercivity will be affected by the introduction of such background field because the dynamic coercivity is significantly higher than the static coercivity.

Fig. 6 illustrates magnetic field simulation results using a boundary element solver, Amperes, for different values of coil current. The field profiles at $I = 50 \text{ mA}$ ($=I_{SAT}$) and $I=200 \text{ mA}$ ($\Delta I = 150 \text{ mA}$) are given. The additional 150 mA of current on top of the saturation current I_{SAT} generates a background field of 4,000 Oe. This background field would not be high enough to erase the previously recorded bit pattern, but it effectively increases the write field of the pole tip, i.e., decreases the effective media coercivity.

A test was conducted to confirm the performance of the present design. Fig. 7 schematically illustrates the test. A conventional perpendicular writer 34 having a magnetic coil 35 placed far from the pole tip 36 or the air bearing surface of the writer was used in combination with an external field source 38 (a strong rare earth-based permanent magnet that could generate stray fields in excess of 2,000 Oe) to simulate a

- 10 -

background field from a coil if the coil was placed in close proximity to the ABS. The recording tests were conducted on a multilayer perpendicular media 30 comprised of twenty layers of Co/Pd on a soft underlayer of FeAlN, having a coercivity in excess of 8,000 Oe. First, the media was DC saturated (DC erased) in a strong magnetic field generated using a large electromagnet. As expected, due to demagnetizing fields, no stray field emanates from the DC saturated media, resulting in zero signal read-out. Next, recording with a conventional perpendicular writer was attempted, which failed due to insufficient magnitude of the recording field. The recording failure was confirmed by the absence of the read-out signal. Finally, a small permanent magnet was placed above the recording head in close proximity to the media, as schematically illustrated in Fig. 7, and another recording attempt was performed. The result was a well-recorded bit pattern with the playback shown in Fig. 8. The results shown in Fig. 8 demonstrate that the anisotropy of the recording media is effectively temporarily lowered by the application of the background magnetic field.

The present recording system effectively reduces the coercivity of the media. This is accomplished by generating a background field utilizing a magnetizing coil which is placed in proximity to the recording layer. This recording system enables writing on high coercivity/high anisotropy media that can support very high recording densities, e.g., in excess of 100Gbit/in². High recording densities can therefore be achieved without the necessity of major changes in the recording process.

Whereas particular embodiments of this invention have been described above for purposes of illustration, it will be evident to those skilled in the art that numerous variations of the details of the present invention may be made without departing from the invention as defined in the appended claims.

WHAT IS CLAIMED IS:

1. A perpendicular recording head for use with a magnetic recording medium, the perpendicular recording head comprising:
 - a main pole having a tip; and
 - an electrically conductive magnetizing coil positioned sufficiently close to the main pole tip to generate a background magnetic field in the magnetic recording medium when current is passed through the magnetizing coil.
2. The perpendicular recording head of Claim 1, wherein the magnetizing coil at least partially surrounds the main pole.
3. The perpendicular recording head of Claim 2, wherein the magnetizing coil comprises a single winding around the main pole.
4. The perpendicular recording head of Claim 2, wherein the main pole is connected to a yoke.
5. The perpendicular recording head of Claim 4, wherein the magnetizing coil at least partially surrounds the yoke.
6. The perpendicular recording head of Claim 5, wherein the magnetizing coil is spaced apart from an outer surface of the yoke.
7. The perpendicular recording head of Claim 5, wherein the magnetizing coil is positioned directly adjacent an outer surface of the yoke.
8. The perpendicular recording head of Claim 5, wherein the magnetizing coil is at least partially embedded in an outer surface of the yoke.
9. The perpendicular recording head of Claim 5, wherein the yoke has a thickness greater than a thickness of the main pole.
10. The perpendicular recording head of Claim 9, wherein the ratio of the yoke thickness to the main pole thickness is less than about 10:1.
11. The perpendicular recording head of Claim 9, wherein the ratio of the yoke thickness to the main pole thickness is from about 2:1 to about 5:1.

12. The perpendicular recording head of Claim 2, wherein the magnetizing coil has a radial dimension R measured from an axis defined by the main pole, the magnetizing coil has a pole tip distance D measured from the magnetizing coil to the pole tip in a direction parallel with the main pole axis, and the ratio of $R:D$ is from about 1:1 to about 10:1.

13. The perpendicular recording head of Claim 12, wherein the ratio of $R:D$ is from about 1:1 to about 10:1.

14. The perpendicular recording head of Claim 12, wherein the radial dimension R is from about 0.1 to about 5 micron.

15. The perpendicular recording head of Claim 12, wherein the pole tip distance D is from about 0.1 to about 5 micron.

16. The perpendicular recording head of Claim 1, wherein the background magnetic field is greater than 100 Gauss.

17. The perpendicular recording head of Claim 1, wherein the background magnetic field is greater than 1,000 Gauss.

18. The perpendicular recording head of Claim 1, wherein the background magnetic field is greater than 2,000 Gauss.

19. The perpendicular recording head of Claim 1, wherein the background magnetic field is from about 5,000 to about 10,000 Gauss.

20. The perpendicular recording head of Claim 1, wherein the background magnetic field has a strength H_b , a magnetic field generated at the main pole tip has a strength H_p , and the ratio of $H_b:H_p$ is from about 1:10 to about 10:1.

21. The perpendicular recording head of Claim 20, wherein the ratio of $H_b:H_p$ is from about 4:10 to about 3:1.

22. The perpendicular recording head of Claim 1, wherein the magnetizing coil generates a magnetic field at the main pole tip in addition to the background magnetic field that is generated when the current is passed through the magnetizing coil.

23. A magnetic recording apparatus, comprising:
a magnetic recording medium including an upper layer having a plurality of data storage tracks, and a lower layer being magnetically soft relative to the data storage tracks; and
a recording head including a main pole having a tip, and an electrically conductive magnetizing coil positioned sufficiently close the main pole tip to generate a background magnetic field in the magnetic recording medium when the recording head is positioned at a flying height above the magnetic recording medium and current is passed through the magnetizing coil.
24. The magnetic recording apparatus of Claim 23, wherein the magnetizing coil at least partially surrounds the main pole.
25. The magnetic recording apparatus of Claim 24, wherein the main pole is connected to a yoke having a thickness greater than a thickness of the main pole.
26. The magnetic recording apparatus of Claim 24, wherein the magnetizing coil has a radial dimension R measured from an axis defined by the main pole, the magnetizing coil has a pole tip distance D measured from the magnetizing coil to the pole tip in a direction parallel with the main pole axis, and the ratio of $R:D$ is from about 1:1 to about 10:1.
27. The magnetic recording apparatus of Claim 24, wherein the background magnetic field has a strength H_b , a magnetic field generated at the main pole tip has a strength H_p , and the ratio of $H_b:H_p$ is from about 1:10 to about 10:1.
28. The magnetic recording apparatus of Claim 23, wherein the magnetizing coil generates a magnetic field at the main pole tip in addition to the background magnetic field that is generated when the current is passed through the magnetizing coil.

- 14 -

29. A method of storing data on a magnetic storage medium, the method comprising the steps of:

- providing a magnetically permeable main pole;
- providing a magnetic storage medium adjacent the main pole;
- directing magnetic flux from the main pole toward the magnetic storage medium; and
- additionally generating a background magnetic field in the magnetic storage medium.

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "Z" document member of the same patent family

Date of the actual completion of the international search

14 November 2000

Date of mailing of the international search report

22/11/2000

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☒ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☐ **GRAY SCALE DOCUMENTS**
- ☐ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☐ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
